

Extending Workload Protection with Microsoft Defender for Cloud

After establishing security posture and baseline controls, the next step is protecting what actually runs in the cloud.

This project focuses on extending workload protection using Microsoft Defender for Cloud, specifically for servers and App Services.

Designing runtime protection for Azure workloads

From Posture to Protection

- Measure posture
- Identify risk
- Protect workloads

Security posture tells us where we are weak, but it does not actively protect workloads. Once posture is understood, architects must decide how to protect compute and applications at runtime. This is where Cloud Workload Protection comes into play.

Posture measures security gaps, but does not stop active threats.

Defender for Cloud: Plan Layers Explained

- Foundational CSPM
- Defender CSPM
- Cloud Workload Protection (CWPP)

Microsoft Defender for Cloud is structured in layers.

Foundational CSPM provides posture visibility.

Defender CSPM adds advanced posture capabilities.

Cloud Workload Protection focuses on protecting workloads such as servers and applications while they are running.

The screenshot shows the 'Settings | Defender plans' page in the Microsoft Azure portal. The left sidebar contains navigation options: Settings, Defender plans (selected), Security policies, Email notifications, Workflow automation, and Continuous export. The main content area is divided into two sections. The first section, 'Defender plans', shows a table with two plans: 'Foundational CSPM' (Free, 0 resources, Full monitoring coverage) and 'Defender CSPM' (\$5/Billable resource/Month, 0 resources, Full monitoring coverage). The second section, 'Cloud Workload Protection (CWPP)', shows a table with various workload types and their protection status. The status for each workload type is currently 'Off'.

Defender for Servers (Architect View)

- VM runtime protection
- Threat detection
- Vulnerability insights
- Endpoint integration
- Agent-based and agentless coverage options

Defender for Servers is designed to protect virtual machines at runtime. It provides threat detection, vulnerability assessment, and integration with Defender for Endpoint.

From an architect's perspective, this is about reducing risk on compute resources that are exposed or business-critical.

Plan Selection & Cost Awareness

- Per-server pricing
- Scope matters
- Enable intentionally

Defender for Servers is a paid, per-server service.

Architects should never enable this blindly.

The decision must consider workload criticality, exposure, and business risk to ensure cost aligns with value.

Defender for App Service (Why It Matters)

- Protects PaaS workloads
- Detects suspicious behavior
- Context-rich alerts

Designed for PaaS where OS-level controls are not accessible.

Defender for App Service extends protection to platform-as-a-service workloads.

It monitors application behavior, identifies attack patterns, and generates contextual alerts.

This is especially important for internet-facing applications where traditional VM-based security does not apply.

The screenshot displays the Microsoft Azure portal interface. The main section is titled 'Settings | Defender plans' for 'Azure subscription 1'. It shows a table of Defender plans:

Plan	Pricing*	Resource quantity
Foundational CSPM	Free	
Defender CSPM	\$5/Billable resource/Month	0 resources

Below this, the 'Cloud Workload Protection (CWPP)' section is expanded, showing a table of plans for various resources:

Plan	Pricing*	Resource quantity
Servers	Plan 2 (\$15/Server/Month)	0 servers
App Service	\$15/Instance/Month	0 instances
Databases	Selected: 0/4	0 instances
Storage	\$10/Storage account/month	0 storage accounts
Containers	\$6.8693/VM core/Month	0 container registries; 0 Kubernetes cores
AI Services	\$0.0008/1K tokens/month	0 AI resources
Key Vault	\$0.25/Vault/Month	0 key vaults
Resource Manager	\$5/Subscription/Month	

On the right, a 'Plan details' overlay for 'App Service' is shown, listing features and pricing:

- Pricing:** \$15/Instance/Month
- Protects applications running over Azure App Service
- Assesses resources covered by your App Service plan and generates security recommendations
- Monitors the VM host of your App Service and its management interface
- Monitors requests and responses sent between App Service apps
- Monitors the underlying sandboxes and VMs
- Monitors App Service internal logs
- Identifies attack methodologies applying to multiple targets
- Generates detailed, context-based, security alerts easily integrated with any SIEM
- Alerts include guidelines to help investigate and mitigate identified threats
- Regulatory compliance and industry best practices

Why These Plans Are Not Always Enabled

- Paid services
- Business approval required
- Architecture before activation

In real enterprise environments, architects don't enable paid security controls without proper scoping and approval.

The role of the architect is to design the protection strategy first, then enable controls when the business is ready.

Architect Decision Matrix

Workload	Enable CWPP?	Reason
Production VMs	Yes	High risk
Dev/Test VMs	Conditional	Cost vs value
App Services	Yes	Internet-facing

Architects evaluate workloads differently.

Production systems usually justify full protection, while development environments may not.

This decision-making process is what turns security tools into an effective strategy.

Key Architect Takeaway

Posture measures risk. Protection reduces risk.

Security posture helps us understand risk, but workload protection reduces that risk. Architects must design both, and enable controls intentionally to balance security, cost, and scale.

Security tools are effective only when paired with architectural intent.

Architect's Perspective

This project focuses on architectural decision-making rather than tool activation.
Real security comes from knowing when and why to enable controls — not just how.
